A production method for producing reactive species $\left(\mathrm{OH}, \mathrm{H}, \mathrm{O}, \mathrm{O}_{3}\right.$ ，and $\left.\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)\right)$ using vacuum ultraviolet （VUV）photolysis with an excimer lamp is proposed．It can be used for studying effects of the reactive species on plasma medicine．Densities of reactive species produced by the VUV method are calculated using a simulation and the validity of the simulation is verified by measuring $\mathrm{O}_{3}$ and OH densities using UV absorption and laser－induced fluorescence．

## 1．Introduction

In plasma medicine，reactive species produced in the plasma are considered to have therapeutic effects．However，the effect of each kind of reactive species on plasma medicine is still not clear because many kinds of reactive species are produced in plasma，and their individual medical effects are difficult to isolate．For investigation of the effects of reactive species on plasma medicine， another production method of reactive species is needed that has a much simpler reaction system than plasma．In this paper，a production method of reactive species using vacuum ultraviolet （VUV）photolysis is proposed．

## 2．Simulations

The VUV method is shown in Fig．1．It is similar to a He atmospheric－pressure plasma jet（APPJ） used for plasma medicine．Helium－buffered mixture $\left(\mathrm{H}_{2} \mathrm{O} / \mathrm{He}\right.$ or $\left.\mathrm{O}_{2} / \mathrm{He}\right)$ flows in a quartz tube of 2 mm diameter．The VUV light from the excimer lamp （ $\mathrm{Xe}_{2}$ lamp at 172 nm or $\mathrm{Kr}_{2}$ lamp at 146 nm ） irradiates the flowing gas near the quartz tube nozzle to photodissociate $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{O}_{2}$ to produce $\mathrm{OH}, \mathrm{H}, \mathrm{O}, \mathrm{O}_{3}$ ，and $\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ ．When an $\mathrm{O}_{2} / \mathrm{He}$ is used， $\mathrm{O}_{2}$ is photodissociated by the VUV light as

$$
\begin{equation*}
\mathrm{O}_{2}+h v \rightarrow \mathrm{O}\left({ }^{1} D\right)+\mathrm{O} . \tag{1}
\end{equation*}
$$

The resulting $\mathrm{O}\left({ }^{1} D\right)$ reacts with $\mathrm{O}_{2}$

$$
\begin{equation*}
\mathrm{O}\left({ }^{1} D\right)+\mathrm{O}_{2} \rightarrow \mathrm{O}+\mathrm{O}_{2}(X, a, b) . \tag{2}
\end{equation*}
$$

$\mathrm{O}_{2}\left(b^{1} \Sigma_{g}{ }^{+}\right)$is deactivated to $\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ as

$$
\begin{equation*}
\mathrm{O}_{2}(b)+\mathrm{M} \rightarrow \mathrm{O}_{2}(a)+\mathrm{M} \tag{3}
\end{equation*}
$$

Fig．1．Schematics of the VUV method．
$\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ is produced via reactions（2）and（3）． O atoms produced by reactions（1）and（2）react with $\mathrm{O}_{2}$ to produce $\mathrm{O}_{3}$

$$
\begin{equation*}
\mathrm{O}+\mathrm{O}_{2}+\mathrm{M} \rightarrow \mathrm{O}_{3}+\mathrm{M} \tag{4}
\end{equation*}
$$

Thus， $\mathrm{O}, \mathrm{O}_{3}$ ，and $\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ are produced as a result of the VUV photodissociation of $\mathrm{O}_{2}$（reaction（1））．

When an $\mathrm{H}_{2} \mathrm{O} / \mathrm{He}$ is used，photodissociation of $\mathrm{H}_{2} \mathrm{O}$ leads to production of OH and H

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{O}+h v \rightarrow \mathrm{OH}+\mathrm{H} \tag{5}
\end{equation*}
$$

Figure 2（a）shows a simulation result when the VUV light from a $\mathrm{Xe}_{2}$ lamp irradiates a $\mathrm{H}_{2} \mathrm{O}(2.8 \%) / \mathrm{He}$ mixture．The simulation is one－dimensional，including 42 photolysis and chemical reactions and 4 wall reactions．The inner diameter of quartz tube is 2 mm ，the gas flow rate is $2 \mathrm{~L} / \mathrm{min}$（ $=1.06 \mathrm{~cm} / \mathrm{ms}$ ），and the illuminance of the

Fig.2. Simulation results for $\mathrm{Xe}_{2}$ lamp and $\mathrm{Kr}_{2}$ lamp methods.
$\mathrm{Xe}_{2}$ lamp is $50 \mathrm{~mW} / \mathrm{cm}^{2}$ which is approximately the maximum illuminance provided by commercially available $\mathrm{Xe}_{2}$ lamps. The VUV light is irradiated for 1 cm length ( $x=0$ to 1 cm in Fig. 2) and the target is assumed to be placed at 0.5 cm from the quartz tube nozzle ( $x=1.5 \mathrm{~cm}$ in Fig. 2). The nozzle is at $x=1 \mathrm{~cm}$. Figure 2(a) shows that 1-2 ppm of H and OH radicals are supplied to the target. The OH density is on the same order of that produced by a He-APPJ [1].

Figure 2(b) shows a simulation result when the VUV light from a $\mathrm{Kr}_{2}$ lamp irradiates an $\mathrm{O}_{2}(0.2 \%) / \mathrm{He}$ mixture. The $\mathrm{Kr}_{2}$ lamp has a large cross section for $\mathrm{O}_{2}$ photolysis, while the $\mathrm{Xe}_{2}$ lamp has a large cross section for $\mathrm{H}_{2} \mathrm{O}$ photolysis. The VUV irradiation length is increased to 5 cm . When the $\mathrm{Kr}_{2}$ lamp ( 146 nm ) is used, a $\mathrm{MgF}_{2}$ of a $\mathrm{CaF}_{2}$ tube should be used instead of the quartz tube. Figure 2 shows that 2 ppm of O atoms are supplied to the target, but it is an order of magnitude smaller than that produced by a $\mathrm{He}-\mathrm{APPJ}$ [1]. If the gas flow rate is reduced to $0.1 \mathrm{~L} / \mathrm{min}$ to increase the VUV light irradiation time, high densities of $\mathrm{O}_{3}$ and $\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ are obtained: higher than 1000 ppm and 10 ppm, respectively, which are equivalent to or higher than those produced by a He-APPJ [2, 3].

## 3. Experiments

To verify the validity of the simulations, the $\mathrm{O}_{3}$ and OH densities produced by the $\mathrm{Xe}_{2}$ lamp method are measured. A Xe 2 excimer lamp (Min-Excimer, Ushio) is used as the VUV source. The $\mathrm{O}_{3}$ density is measured using 254 nm absorption from a low-pressure mercury lamp when dry or humid $\mathrm{O}_{2}(0-100 \%) / \mathrm{He}$ mixture is irradiated with the $\mathrm{Xe}_{2}$
lamp, and the OH density is measured using laser-induced fluorescence (LIF) at 2 mm distance from the quartz tube nozzle when $\mathrm{H}_{2} \mathrm{O}(2.8 \%) / \mathrm{He}$ is irradiated with the $\mathrm{Xe}_{2}$ lamp. The measured $\mathrm{O}_{3}$ densities are slightly higher than the simulated results but the difference is within $35 \%$. It is allowable. The difference for OH density is 3-4 times, which is not negligible but understandable if measurement errors are considered.

## 4. Conclusions

The production of $\mathrm{OH}, \mathrm{H}, \mathrm{O}, \mathrm{O}_{3}$, and $\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ using the VUV photodissociation of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{O}_{2}$ was proposed. It was studied using simulations and measurements. The VUV method produced sufficient amount of $\mathrm{OH}, \mathrm{O}_{3}$, and $\mathrm{O}_{2}\left(a^{1} \Delta_{g}\right)$ compared with He-APPJ. However, the density of O atoms was much smaller than He-APPJ. Instead of the VUV method, we are at present developing another method for O atoms production. According to a simulation, the alternative method can supply more than 100 ppm of O atoms continuously to a target. We are now planning experiments to verify the simulation of the method.
